# Outline

---

- We describe the ePLAS model used for our calculations.
- We compare shock development with *artificial* and *real* viscosity in Cartesian and spherical implosive flows.
- We examine self-consistent  $E$ - and  $B$ -field effects.
- We show that the real viscosity can spread small scale shocks affecting their collapse dynamics.

# The RAC e-PLAS code

---

## Features:

2-D, fluid ions and electrons with inertia, *artificial* or *real* ion viscosity, electron & ion thermal conductivity, ion & electron thermal coupling, bremsstrahlung, external piston velocity drive, *Implicit Moment E- & B-fields*, relativistic electron corrections.

## Special Capabilities:

- High target densities ( $>10^{25}$  e-/cm<sup>3</sup>) and vacuum regions.
- No  $\Delta t$  restraint from  $\omega_p \Delta t < 1$ , allowing *large scale problems*.
- Alternate ion and electron particle modelling (fluids here).

## Richtmeyer & Morton used artificial viscosity to fix shock thicknesses “at about $(3-4)\Delta r$ ”

---

- P. 312: ... “with ordinary” (*real*) “viscosity, in which the stress is proportional to the rate of shear, and which is therefore represented by linear terms in the differential equations, the thickness of the transition layer varies with the shock strength, approaching zero for a very strong shock and infinity for a very weak one. But we wish the thickness to be about the same—namely, about  $(3-4)\Delta r$ —for all shocks, and we therefore” (artificially) “add *quadratic* terms to the differential equation ; this is equivalent to using a small viscosity coefficient for weak shocks and a large one for strong shocks. It will be shown below that we achieve a thickness independent of the shock strength.”

# A real viscous pressure is more fundamental

---

$Q_{qz} = -K_{qz} \partial/\partial z(u_i)$ , spreads  $u_i$  with  $\partial u_i/\partial t = -\partial/\partial z(Q_{qz})/(n_i m_i)$ ,  
in which  $K_{qz} = (m_i n_i v_{th} \Lambda_{ii})$ ,  $\Lambda_{ii} = v_{th}/v_{ii}$ , and  $v_{ii} \sim n_i/T_i^{3/2}$ . (Here  
 $z$  is the axial direction in 2D problems.)

So, there is  $n_i$  independence in  $K_q$ , but as  $T \uparrow$  we get  $v_{ii} \downarrow\downarrow$ .

Tenuous regions can heat readily, implying very broad viscous spreading of the flow.

We have chosen to “flux limit” such stress effects to multiple  
( $f \sim 20$ ) cells:  $f\Delta z$ .

# Run parameters

---

- We will explore a 20-40  $\mu\text{m}$  scale test region in Cartesian and spherical geometries.
- A DT ion plasma at 1.2 keV with fluid electrons evolves for up to 26 ps, producing a contact surface, shocks, and spherical convergence.
- Driving shell densities are from  $5 \times 10^{23}$  to  $2 \times 10^{25}/\text{cc}$  with voided “core” densities from  $7 \times 10^{19}$  to  $5 \times 10^{22}/\text{cc}$ .
- The mesh uses 50 to 100 cells for 2D cylindrical (spherical) simulations.

# Ultimately we will be interested in the core shock dynamics of NIF-like ICF targets

# Real viscosity produces diffusing fronts instead of steep shocks in low density planar target voids

## Conventional *artificial* viscosity for 1.2 keV drive – ions only

## *real* physical viscosity

Cartesian geom

Plasma Physics

RAC

# Such spreading with *real* viscosity continues when *E*-fields from $e^-$ pressure are introduced

with conventional *artificial* viscosity at 17 ps

with *real* physical viscosity

# But with a *10 x larger flow scale* there is little viscous model effect on the shock structure

# Spherical implosions show a similar *small scale* dependence on the viscosity model

**artificial viscosity @ 9.3 ps**

**real viscosity**

# Elliptical DT target implosions show a strong viscosity dependence (here: for *artificial* visc)

Initially  $T_i = 1.2$  keV. Note the shocked ring development.

# While with *real* viscosity, we see compression and an $l = 2$ central voided feature + shocks

# The associated *art* viscosity axial density profile shows shock convergence and rebound

**$t = 0.$**

**7.9 ps**

**12.1 ps**

**26 ps**

# ***Real* viscosity also gives a smoother lower, central density profile at peak compression**

**t = 0.**

**7.9 ps**

**16.1 ps**

**26 ps**

# **Art viscosity gives a spiked central temperature and density - with *real* visc these are smeared**

**artificial viscosity @ 7.9 ps**

**real viscosity @ 16.1 ps**

# Central $B$ -fields in the target core are twice as large with *real* viscosity

*real* viscosity @ 26 ps

*artificial* viscosity

# With imploding densities near $1000 \text{ g/cm}^3$ spherical core conditions depend on the viscous model

**art viscosity**

**$t = 5.3 \text{ ps}$**

**7.3 ps**

**10 ps**

**16.7 ps**

**real viscosity**

# The corresponding axial densities evolve from the driving 1000 g/cm<sup>3</sup> densities as:

**t = 5.3 ps**

**7.3 ps**

**10 ps**

**16.7 ps**

**artificial viscosity**

**real viscosity**

# In NIF-like Implosions with initial inward shell drive *real* viscosity produces diffused shocks

**t = 15.5 ps**

**27.3 ps**

**54.6 ps**

# While *art* viscosity gives traditional steep shocks

**t = 15.5 ps**

**23.5 ps**

**54.7 ps**

**However, with a 350 eV shell and a  $0.75 \mu/\text{ps}$  piston both viscous models give  $\sim 1000 \text{ g/cc}$  density peaks**

**art visc**

**real visc**

peak density

diffused shocks

# A rough inner shell surface doesn't appear to change the acquired "peak" conditions

**t=0**  
**10 $\mu$  surface**  
**perturbation.**

**real visc, 25.5 ps**

**art visc, 21.8 ps**

# Conclusions

---

- Replacing the usual *artificial* viscosity with a *real* version can significantly alter small scale implosion dynamics, accessing some of the new physics that would be embodied in a kinetic treatment.
- 2D spherical effects are readily accessed at minimal additional expense.
- General use of *artificial* viscosities may have lead overly optimistic predictions for NIF targets or, at least, inappropriate pulse shape tunings.
